Incident Label Provenance and Leakage Assessment by Class

This table summarizes how Cloudflare Radar labels entered the final corpus and how the audit distinguished external label provenance from documented evidence-source overlap.

Incident Class	External Label Source	Cloudflare Feed Endpoint	Local Label Assignment	Evidence Source Overlap	Direct Target Leakage
Hijack	Cloudflare Radar BGP Hijack Events feed	/radar/bgp/hijacks/events	Assigned Hijack because event came from the hijack feed	Documented overlap with public BGP, RPKI/IRR, AS-path, and AS-relationship evidence	None detected
Leak	Cloudflare Radar BGP Route Leak Events feed	/radar/bgp/leaks/events	Assigned Leak because event came from the route leak feed	Documented overlap with BGP AS-path and AS-relationship/valley-free evidence	None detected
Outage	Cloudflare Radar outage annotations	/radar/annotations/outages with eventType = OUTAGE	Assigned Outage because record was an outage annotation and passed local ASN/network quality filters	Broader Internet outage annotation; not a BGP-specific outage detector	None detected

Note. Direct target leakage was not detected. Evidence-source overlap is documented because Cloudflare and the model both observe manifestations of the underlying routing event.
